Brevini[®] Planetary Gearboxes **S Series**

Torques from 11.800 ft-lb to 811.300 ft-lb

Industrial solutions

Brevini[®] S Series planetary gearboxes are designed to ensure effective performances and quiet operation in multiple possible configurations.

Brevini Industrial Series

The Brevini Industrial series is a complete range of modular planetary gearboxes that combines high performance with low cost and size. The commercial success this range has achieved for more than 40 years testifies to its quality, reliability, ease of installation and low maintenance requirements.

Brevini Industrial series covers a full range of sizes that ensure optimum durability, quiet operation in all working conditions and efficiency to reduce operating costs and maximise availability.

The ISO 9001:2000 quality system for design, development, production, assembly and after-sales service guarantees a high supply standard at an international level.

The Brevini Industrial Series

The modular transmission system offers customers various benefits, including:

- Short lead times due to a high level of standardisation
- The torque is distributed proportionately among the sizes means the most suitable gearbox can be selected for every application
- High product quality
- Numerous available variants allow more flexible configuration for a wide range of applications
- Customised variants based on the modular system

Available options:

- From 1 to 4 planetary stages with the in-line configuration
- From 2 to 4 stages with the right-angle configuration
- Configurations with more stages are available on request
- 9 sizes based on the principle of modularity

Construction and Design:

- Keyed cylindrical shafts: male and female
 - Splined shafts: male and female
 - Female cylindrical shaft with retaining ring
- Horizontal and vertical installation possible

Output torques

T_{2N} from 25000 ftlb to 390000 ftlb

Ratios:

- $i = 3.4$ up to 3000 with the in-line configuration
- $i = 10$ up to 3000 with the right-angle configuration
- $i > 3000$ by combining more than 4 planetary stages

Casings

The Brevini Industrial series casings basically consist of an input flange, reduction stages, intermediate coupling flanges and output supports.

They are dimensioned to suit the loads transmitted through the gearbox, which increase from the input to the output.

Casing materials:

- Input supports: EN-GJL-250 grey cast iron
- Rim: high-quality hardened steel
- Intermediate coupling flange: EN-GJS-400-15 spheroidal-graphite cast iron
- Output supports: EN-GJS-400-15 spheroidal-graphite cast iron

Output shafts:

- Solid shaft, keyed or splined according to DIN5482
- Hollow shaft, keyed, splined according to DIN5482 or with keyway

Available inputs:

- Direct coupling with adapter flange for electric and hydraulic motors
- Keyed solid shaft
- SAHR (Spring Applied Hydraulically Released) brakes

Gears

The Brevini S series uses gears designed to optimise load distribution and minimise noise. The case-hardening processes are applied to the gears in-house to ensure control over the entire production process.

Bearings:

Only Class A bearings are used in the planet carriers to ensure that they meet the durability criteria required for industrial applications.

Seals:

The following sealing systems are available as standard for the input and output shafts:

- NBR and FKM radial shaft seals, VMQ on request
- Taconite seals on input and output shafts exposed to harsh environmental conditions

Lubrication:

- Oil bath lubricated gears and roller bearings as standard
- Sight glass plug as standard for vertical mounting configurations

Accessories:

Output:

Available for male splined output shaft:

- Wheel flange
- Sleeve
- Tab washer

Available for female hollow output shaft:

- Keyway
- Tab washer

Available for female splined output shaft:

- Splined rod

Input:

- Anti-backlash devices

General:

- Quoted dimensional drawings are available as CAD files for various computer systems and interfaces
- Digital programs for selecting units
- Gear, shaft and bearing calculations with calculation proof
- Surface protection: painting cycles according to ISO 12944

Noise level:

- The gearbox noise level may vary with the size and number of stages, so no specific value has been declared
- If the noise does not cause abnormal vibration or overheating, do not consider it to be a risk for the application
- Unless specifically requested by the customer during the selection process or while developing the gearbox, the gearbox noise is not considered for design purposes
- Warranty claims related to noise will be assessed case-by-case

Nominal output torque T_{2N} [ftlb]

This is the conventional output torque that defines the size of the gearbox.

Transmissible output torque T_2 [ftlb]

This is the output torque that the gearbox can transmit with a uniform and continuous load (duty factor $fs=1$), for different values of gearbox input speed and a **duration of 10000 hours**.

The T_2 values are calculated according to ISO 6336 for the gears and ISO 281 for the bearings, and are given in the size selection tables.

Max output torque T_{2MAX} [ftlb]

This is the peak transmissible output torque that a gearbox can provide for short periods. For drives involving a high number of starts or reversals, the maximum operational torque must also be limited to suit the strength of the gears or shafts. The T_{2MAX} values are given in the size selection tables.

Required output torque T_{2R} [ftlb]

This is the output torque required by the application, which must always be less than the transmissible output torque T_2 of the selected gearbox.

Required maximum output torque T_{2RMAX} [ftlb]

This is the maximum output torque required by the application, which must always be less than the maximum transmissible output torque T_{2MAX} of the selected gearbox.

Input braking torque T_B [ftlb]

This is the static braking torque delivered by the multi-disc brake that may be installed on the gearbox input. The T_B values for the various brake configurations are given in the "Oil bath multi-disc brakes" section.

Required input braking torque T_{BR} [ftlb]

This is the braking torque required at the gearbox input if the application involves the use of an input brake. It can be calculated with the following equation:

$$T_{BR} = \frac{S_i \times T_{2R}}{i} \quad \text{[ftlb]} \quad (1)$$

where

- S_i is the brake safety factor
- T_{2R} is the required output torque
- i is the reduction ratio

The brake safety factor S_i depends on the type of application and must be specified by the customer. Sometimes its minimum value is indicated by specific regulations relevant to the application.

Input speed n_1 [rpm]

This is the speed of the motor coupled to the gearbox or, in general, the speed of the gearbox input stage. For drives with pulleys and belts, for example, its value must take the reduction ratio into account.

Max input speed n_{1MAX} [rpm]

This is the maximum gearbox input speed for short periods or for intermittent duty. The gearbox may remain at a speed of n_{1MAX} for a maximum of 1 minute followed by a cooling period. If longer periods at that speed are expected and/or higher speed values are foreseen, we recommend contacting the Dana Sales Department.

The n_{1MAX} values are given in the selection tables.

*i***Output speed n_2 [rpm]**

This is the gearbox output speed. It can be calculated with the following formula:

$$n_2 = \frac{n_1}{i} \quad [\text{rpm}] \quad (2)$$

where n_1 is the input speed and i is the gearbox reduction ratio.

Reduction ratio i

This is the ratio between the input speed n_1 and output speed n_2 .

$$i = \frac{n_1}{n_2} \quad (3)$$

Input power P_1 [HP]

This is the power applied to the gearbox input. It can be calculated with the following formula:

$$P_1 = \frac{P_2}{\eta_d} \quad [\text{HP}] \quad (4)$$

where

- P_2 is the output power
- η_d is the dynamic efficiency of the gearbox, the value of which is given in the table (4)

Output power P_2 [HP]

This is the power transmitted at the gearbox output. It can be calculated with the following formula:

$$P_2 = \frac{T_{2R} \times n_2}{5200} \quad [\text{HP}] \quad (5)$$

where T_{2R} is the required output torque and n_2 is the output speed.

Thermal power P_T [HP]

This is the power that the gearbox can transmit continuously in the following conditions:

- with splash lubrication, without an auxiliary cooling circuit
- with horizontal mounting
- at an input speed of 1500 rpm
- for a maximum oil temperature of 176 °F (oil viscosity ISO VG150)
- at an ambient temperature of 68 °F
- for use in a "large environment"

The P_T values are given in the tables for selection of the various sizes.

If the type of operation, mounting position, input speed, ambient temperature or operating environment are different from those indicated above, it is advisable to use the factors f_K , f_V and f_R given below to correct the thermal power.

Thermal factor f_K

With work cycles that involve intermittent gearbox use and/or an ambient temperature other than 68 °F, the gearbox thermal rating can be adjusted to the specific application with the factor f_K given in the table below.

	Duty cycle I [%]	Ambient temperature [°F]				
		50°	68°	86°	104°	122°
		f_K	100	1.15	1	0.85
	80	1.25	1.1	1	0.85	0.7
	60	1.4	1.25	1.1	1	0.85
	40	1.6	1.4	1.25	1.1	1
	20	1.8	1.6	1.4	1.25	1.1

Tab.(1)

The duty cycle I can be calculated as follows:

$$I = \frac{t_r}{t_r + t_f} \times 100 \quad (6)$$

where t_r is the operating time at constant power and t_f is the rest time.

Speed factor f_v

If the input speed is not 1500 rpm, the thermal power can be adapted to the specific situation with the factor f_v given in the table below. The table refers to the different gearbox mounting positions.

	Mounting position	n_1 [rpm]					
		3000	2500	2000	1500	1000	700
f_v	Horizontal mounting	0.50	0.65	0.80	1.00	1.15	1.30
	Vertical mounting	0.40	0.48	0.58	0.71	0.88	1.00

Tab.(2)

Environmental factor f_R

If the gearbox is located in a restricted space or outdoors, the thermal power can be adapted with the aid of the factor f_R given in the table below.

	Restricted environment	Large environment	Outdoors
f_R	0.70	1.00	1.35

Tab.(3)

In general, the corrected thermal power of the gearbox will be

$$P_{T1} = P_T \times f_K \times f_v \times f_R \quad [\text{HP}] \quad (7)$$

The power P_1 applied to the gearbox must always be less than the corrected thermal power P_{T1} .

$$P_1 \leq P_{T1} \quad (8)$$

If the thermal power of the gearbox is less than the power applied, even in just one possible operating cycle condition, an auxiliary cooling circuit must be provided.

In such conditions, the thermal power to be dissipated P_c can be calculated with the following equation:

$$P_c = (P_1 - P_{T1}) \times (1 - \eta_d) \quad [\text{HP}] \quad (9)$$

where η_d is the dynamic efficiency of the gearbox given by the table (4).

i **Temperature** [°F]

The recommended ambient temperature is in the range -4°F/+104°F. The ideal gearbox operating temperature is from 122°F to 158°F, which corresponds to an oil temperature of approximately 140°F to 176°F. For short periods, the oil temperature can reach 194°F.

The best system to keep the temperature under control is to use an auxiliary heat exchange system.

For low ambient temperatures, or for applications involving high operating temperatures, select appropriate lubricants and seals made of suitable materials.

Seals made of different types of elastomer, such as nitrile butadiene (NB), fluoride (PF) and silicone(SI), are available for this purpose.

Contact the Dana Sales Department for the relevant indications. The "Lubrication" section contains advice on choosing the most appropriate lubricant for different conditions.

Dynamic efficiency η_d

This is given by the ratio between the output power P_2 transmitted by the gearbox and power P_1 applied at the input, and can be calculated with the following formula:

$$\eta_d = \frac{P_2}{P_1} \quad (10)$$

Its value depends on many factors, including: transmitted power, input speed, lubricant viscosity, operating temperature and reduction ratio. The table below gives the approximate dynamic efficiency values.

	Reduction stages			
	1	2	3	4
	EM	ED - EC	ET - EC	EQ - EC
η_d	0.98	0.96	0.94	0.92

Tab.(4)

Duty factor f_s

The duty factor depends on the type of prime mover and the type of machine driven by the gearbox. This is an empirical value drawn from experience with various applications, and takes into account load variations, transmission shocks and the variation uncertainty related to the parameters involved in power transmission.

The table below gives the duty factor values according to the nature of the load, the type of drive (electric, hydraulic and endothermic motor) and the number of starts per hour of the driven machine.

	Nature of the load	Drive type	No. of starts/h				
			16	32	63	125	250
f_s	a Smooth	Electric mot.	1.05	1.10	1.15	1.25	1.40
		Hydraulic mot.	1.05	1.05	1.10	1.15	1.20
		Endothermic engine	1.25	--	--	--	--
	b Variable with moderate shocks	Electric mot.	1.10	1.15	1.20	1.40	1.60
		Hydraulic mot.	1.05	1.00	1.10	1.20	1.30
		Endothermic engine	1.50	--	--	--	--
	c Variable with strong shocks	Electric mot.	1.20	1.30	1.40	1.60	1.80
		Hydraulic mot.	1.10	1.20	1.25	1.35	1.50
		Endothermic engine	2.00	--	--	--	--

Tab.(5)

Regarding the nature of the load, the table below (6) classifies the most common machines into the three levels **a**, **b** and **c** given in the previous table (5).

Nature of the load	Application field		Driven machine	
a	Stirrers/Mixers		Liquids	
b			Semi-liquids	
b			Non-homogeneous liquid	
b	Stone and clay processing		Brick presses	
b			Tile machine	
c			Compactors	
a	Conveyors		Screw	
a			Fed smoothly	
b			For continuous cycle	Not fed smoothly
b				With motion reversal
c	Crane	Port	Load lifting	
c			Auxiliary lifting	
c			Arm lifting	
c			Arm rotation	
c			Crane travel	
c			Container	Container lifting
c			Arm lifting	
c		Industrial applications	Main lifting	
c			Auxiliary lifting	
c			Bridge

c	Sugar processing		Beetroot slicer
b			Cane crushers
b			Shredders
b			Grinders

Tab. (6)

Lifetime factor

$$L_{n_1} \cdot L_{n_2}$$

This is the product of the gearbox input speed n_1 or output speed n_2 and the hours of operation required by the application h_R :

$$L_{n_1} = n_1 \times h_R \quad (11)$$

$$L_{n_2} = n_2 \times h_R \quad (12)$$

Click **DANA** button to return to section index

Permissible radial loads on output / input shafts F_{r2}, F_{r1} [N]

For each gearbox size, the selection tables give the diagrams of permissible radial loads F_{r2} and F_{r1} on the output and input shafts respectively as a function of the distance X between the load application point and the shaft shoulder; the values are given for various values of bearing duration factor n_2xh .

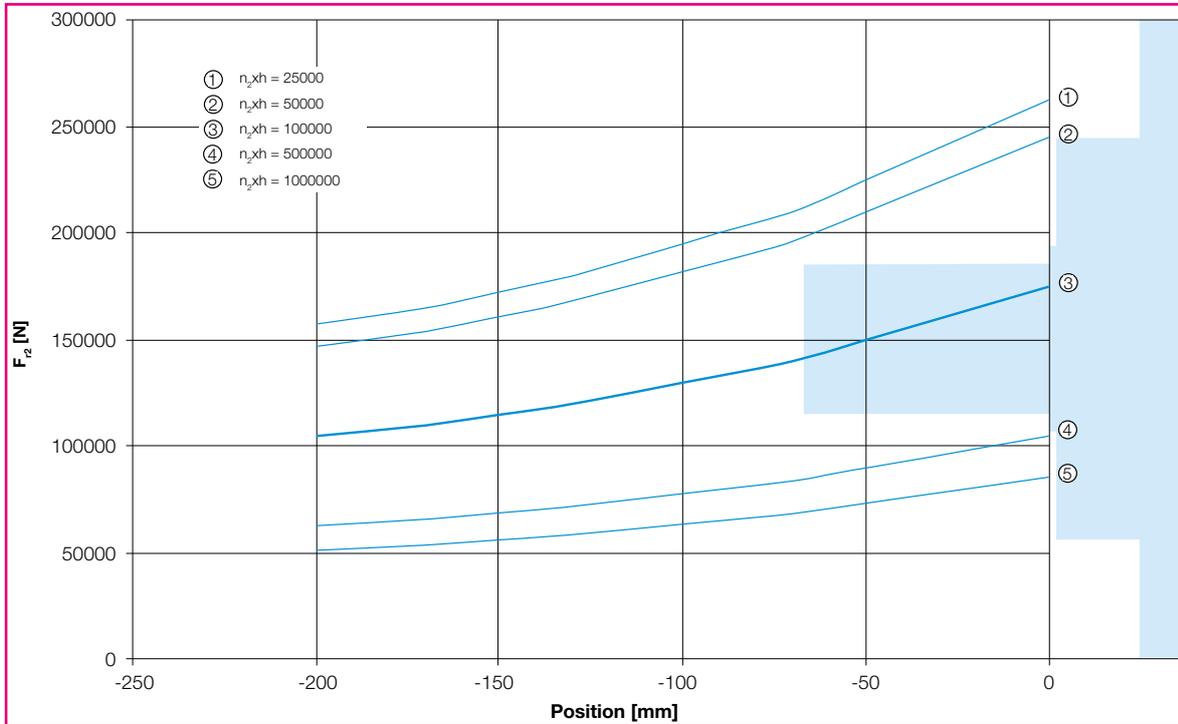

Fig. (1)

Contact the Dana Sales Department for duration factors $n_2xh < 25000$ cycles.

For sizes 150, 155, 250 and 255, the radial loads on output supports MN, MN1, MR and MR1 only apply if both support spigots are used on the customer's structure.

Contact the Dana Sales Department if the second spigot is not used.

Permissible output shaft axial loads F_{a2} [lbf] and F_{a2MAX} [lbf]

For each gearbox size, the tables give the permissible axial loads F_{a2} for continuous duration and F_{a2MAX} for intermittent duration.

If there are radial and axial loads on the output shaft at the same time, we recommend contacting the Dana Sales Department.

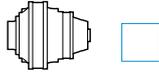

FE and FET gearboxes with female output shafts are normally used to transmit torque only, and are not designed to withstand radial and/or axial loads.

When using FP, FP1 and FS gearboxes with hollow shafts, contact the Dana Sales Department if there are axial loads.

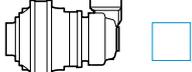

The characteristic application data is required when selecting the gearbox; the list below can be used for that purpose.

Type of application:			
	Description	Value	
T_{2R}	Required output torque		[ftlb]
T_{2RMAX}	Required maximum output torque		[ftlb]
n_2	Output speed		[rpm]
n_1	Input speed		[rpm]
P_2	Output power		[HP]
F_{rR2}	Required radial load on the output shaft		[N]
X_2^*	Radial load F_{rR2} application distance		[in]
F_{aR2}^{**}	Required axial load on the output shaft		[N]
F_{rR1}	Required radial load on the input shaft		[N]
X_1^*	Radial load F_{rR1} application distance		[in]
h_R	Required duration		[h]
I	Duty cycle		[%]
N	Number of starts per hour		[1/h]
t_a	Work environment temperature		[°F]

Type of configuration required:

In-line

Right-angle

Output support type:

Parking brake: Yes No

T_{BR}	Required braking torque:		[ftlb]
----------	--------------------------	--	--------

Mounting position:

Motor type:

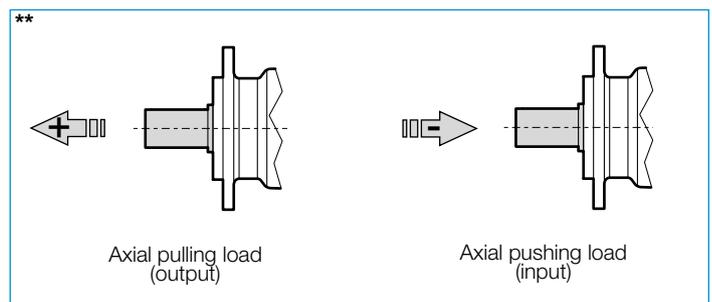

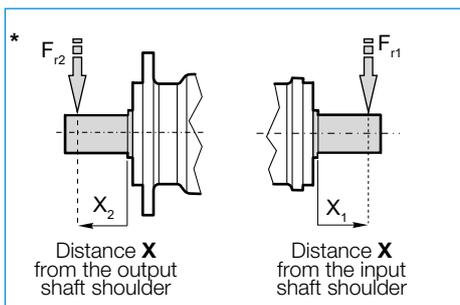

Hydraulic Electric Endothermic Other

Work environment:

Restricted Large Outdoors

* **X** is the distance between the load application point and the shaft shoulder (see diagrams in the selection tables)

** indicate the gearbox output loads with "+" and the input loads with "-".

Click **i** button to return to main index

Click **DANA** button to return to section index

Make the selection as indicated below:

- select the appropriate duty factor f_s from the tables (5) and (6) above on the basis of the application, drive type and expected number of starts;
- calculate the required duration factor from the required duration h_R and the output speed n_2 ;

$$L_{h2} = n_2 \times h_R \quad (13)$$

- calculate the required reduction ratio;

$$i = \frac{n_1}{n_2} \quad (14)$$

- from the selection tables, choose the gearbox and configuration (in-line or right-angle) whose specifications satisfy the equation;

$$T_{2R} \times f_s \leq T_2 \quad (15)$$

The chosen gearbox must have a reduction ratio as close as possible to the required ratio.

This type of selection is suitable when the required torque and rotation speed are almost constant during use; for an operating cycle with highly variable loads and speeds, base the selection on the gearbox size that is best for the application. To do this, we recommend contacting the Dana Sales Department.

If a multi-disc brake is required at the gearbox input, proceed as follows:

1. calculate the required braking torque T_{BR} using the formula (1) on page A5;
2. from the brake selection tables (see the "Oil bath multi-disc brakes" section), choose the brake with the braking torque T_B that satisfies the equation:

$$T_{BR} \leq T_B \quad (17)$$

After selecting the gearbox, carry out the following checks:

- check that the input speed n_1 required by the application is lower than the maximum permissible value n_{1MAX} given in the gearbox selection table
- check that the maximum torque required by the application T_{2RMAX} is lower than the maximum permissible torque T_{2MAX} given in the gearbox selection table
- check that the radial loads acting on the shafts F_{rR1} and F_{rR2} are lower than those given in the gearbox support selection table. The radial loads on the output shaft can be calculated as follows:

$$F_{rR2} = \frac{24 \times T_{2B} \times f_s \times c}{d} \quad [\text{lbf}] \quad (18)$$

The radial loads on the input shaft can be calculated as follows:

$$F_{rR1} = \frac{24 \times T_{2B} \times f_s \times c}{d \times i \times \eta_d} \quad [\text{lbf}] \quad (19)$$

Where T_{2R} is the required output torque, f_s is the duty factor and η_d is the dynamic efficiency of the gearbox. Also,

c is a constant that depends on the type of transmission element mounted on the shaft. The constant can have the following values:

- c = 1 chain pinions
- c = 1.06 gear wheels
- c = 2 belt pulleys

d is the diameter (in) of the transmission element mounted on the shaft.

Using the value X_2 , refer to the output support selection tables for the selected gearbox, locate the permissible radial load F_{r2} for a duration factor $n_2 \times h \geq L_{r2}$ and check:

$$F_{rR2} \leq F_{r2} \quad (20)$$

Similarly, using the value X_1 , refer to the input support selection tables for the selected gearbox, locate the permissible radial load F_{r1} for a duration factor $n_1 \times h \geq L_{r1}$ and check:

$$F_{rR1} \leq F_{r1} \quad (21)$$

check that the axial loads on the output shafts F_{aR2} are lower than those given in the output support selection tables. To do so, refer to the support selection tables for the selected gearbox, identify the permissible load for continuous and intermittent duration, F_{a2} and F_{a2MAX} respectively, and check that:

$$\begin{aligned} F_{aR2} &\leq F_{a2} && \text{for continuous duration} \\ F_{aR2} &\leq F_{a2MAX} && \text{for intermittent duration} \end{aligned} \quad (22)$$

If the radial and axial loads vary significantly during use, or the application involves numerous reversals, contact the Dana Sales Department for a more thorough check.

Take into account the recommendations given in the "Permissible loads on output shafts" section (page A12).

Check that the applied power P_1 is always lower than the corrected thermal power P_{T1} given by the formula (8). If the corrected thermal power of the gearbox is less than the power to be transmitted, even in just one of the possible operating cycle conditions, an auxiliary cooling circuit must be provided. Contact the Dana Sales Department to select this circuit.

If an input brake has been selected for the gearbox concerned, check that the calculated gearbox output braking torque is less than the maximum output torque T_{2MAX} transmissible by the gearbox:

1. calculate the gearbox output braking torque

$$T_{2B} = T_B \times i \quad [\text{ftlb}] \quad (23)$$

2. check that

$$T_{2B} \leq T_{2MAX} \quad (24)$$

This section provides some general information that is useful for selecting the gearbox drive motor.

Hydraulic motor

Based on the application, choose the most appropriate type of motor according to the table below. The values are only a guide

Type of application	Light		Medium		Heavy	
Operating pressure p_A [psi]	< 2500		2500 – 3600		3600 – 6500	
Motor type	Orbital	Gear	Radial piston	Axial piston	Cam	Axial piston
Speed n_1 [rpm]	< 700	< 3000	< 500	< 4000	< 200	< 4000
Mechanical efficiency η_{mh}	0.80	0.85	0.95	0.93	0.93	0.93
Volumetric efficiency η_v	0.90	0.87	0.95	0.95	0.95	0.95

Tab. (7)

Determine the required gearbox input torque with the formula:

$$T_{1R} = \frac{T_{2R}}{i \times \eta_d} \quad [\text{ftlb}] \quad (25)$$

Where T_{2R} is the required output torque and η_d is the dynamic efficiency of the gearbox (table 4)

Calculate the theoretical displacement required for the hydraulic motor with the following formula:

$$V_R = \frac{74 \times T_{1R}}{p_A \times \eta_{mh}} \quad [\text{in}^3] \quad (26)$$

where η_{mh} is the mechanical efficiency of the selected hydraulic motor (table 7) and p_A is the operating pressure of the motor. The actual motor displacement V must be such that:

$$V_R \leq V \quad (27)$$

Lastly, calculate the required flow q for the motor feed:

$$q = 0.0043 \times \frac{V \times n_1}{\eta_v} \quad [\text{gal/min}] \quad (28)$$

where n_1 is the gearbox input speed and η_v is the volumetric efficiency of the chosen motor (table 7).

Refer to the Dana Fluid Power catalogue, or the technical data sheets of other manufacturers for the final motor choice.

Electric motor

Calculate the gearbox input power with the formula:

$$P_1 = \frac{P_2}{\eta_d} \quad [\text{HP}] \quad (29)$$

Where P_2 is the output power and η_d is the dynamic efficiency of the chosen gearbox (table 4).

From the technical data tables of the manufacturers of electric motors, select a motor whose nominal power P_n is such that:

$$P_1 \leq P_n \quad (30)$$

Unless otherwise specified, the power P_n refers to continuous duty S1. If the operating conditions of the motors are different from S1, identify the corresponding type of duty according to the EN 60034-1 (CEI 2-3)/IEC 34-1 standards.

For S2 and S3 with motor sizes smaller than or equal to 132, a suitable factor f_1 can be used to obtain the power increase relative to continuous duty S1.

The power increase factor f_1 can be obtained from the following table:

	Type of duty							
	S2				S3			
	Cycle duration [min]				Duty cycle I [%]			
	10	30	60	90	15%	25%	40%	60%
f_1	1.4	1.2	1.1	1.05	1.4	1.25	1.13	1.07

Tab. (8)

For the definition of the duty cycle I, refer to the formula (6) on page A7.

For duty S2 and S3, select an electric motor whose nominal power P_n satisfies the following equation:

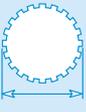

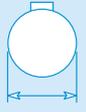

$$P_1 \leq P_n \times f_1 \quad (31)$$

Integral input version - inline version

Input shafts described below are used when the driving motor, which is usually electric, is connected to the input shaft by flexible coupling or belts and pulleys. Normal mounting position is with horizontal axis; for different positions the lubrication solution must be adjusted: please consult the Dana area contact person. Max working speed is generally 1800 min⁻¹.

The input shafts ISL are suitable for connection with elastic coupling. These types are suitable for using on specific gears types, as shown in the dimensional table of each gear size.

Male supports for universal inputs

SU/SUF types are generally used with a flexible coupling. They can be mounted directly to any type of gearbox with universal input 00, and can be supplied separately. See the gearbox section for the dimensions and radial loads.

Universal inputs

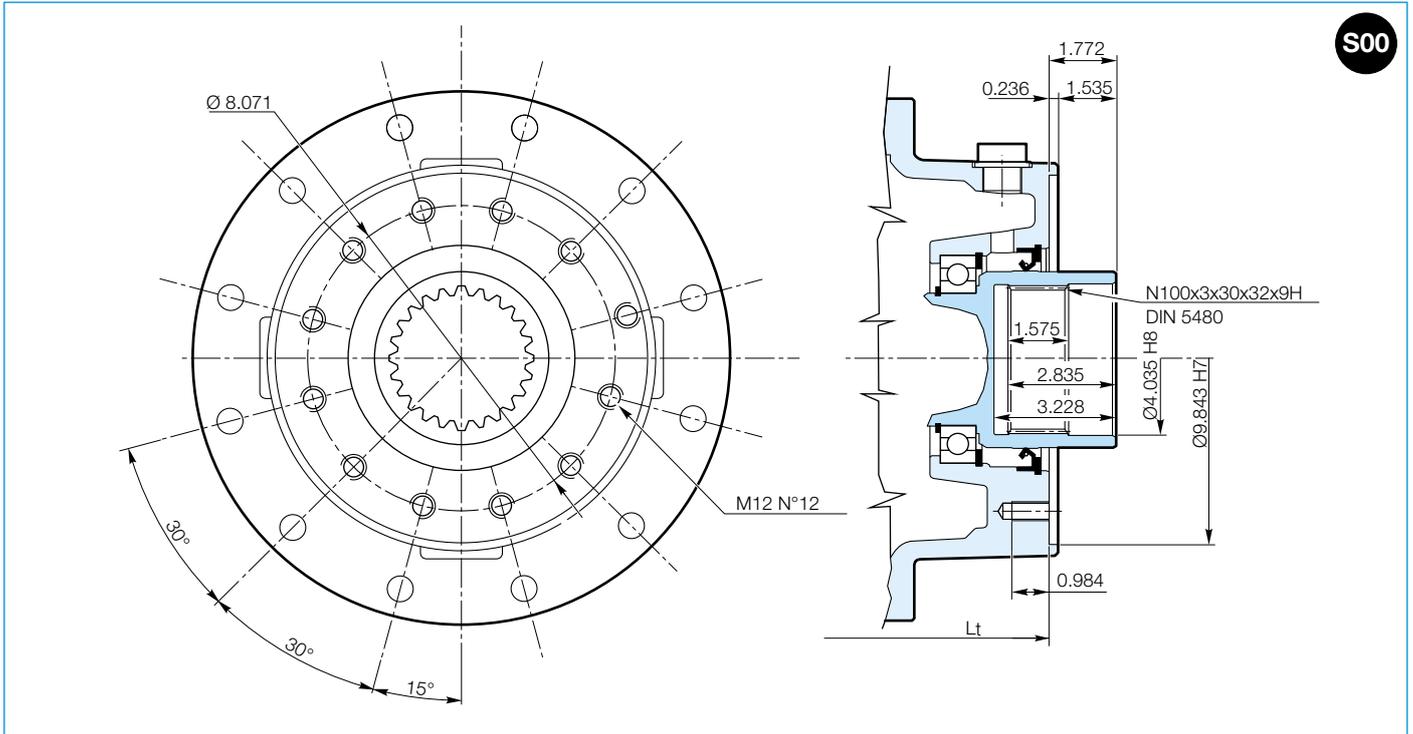

The universal input is a configuration mounted on the gearbox input so that various types of drives can be coupled by means of a special flange and adapter sleeve.

There are two different universal input sizes, depending on the size mounted as the gearbox input stage.

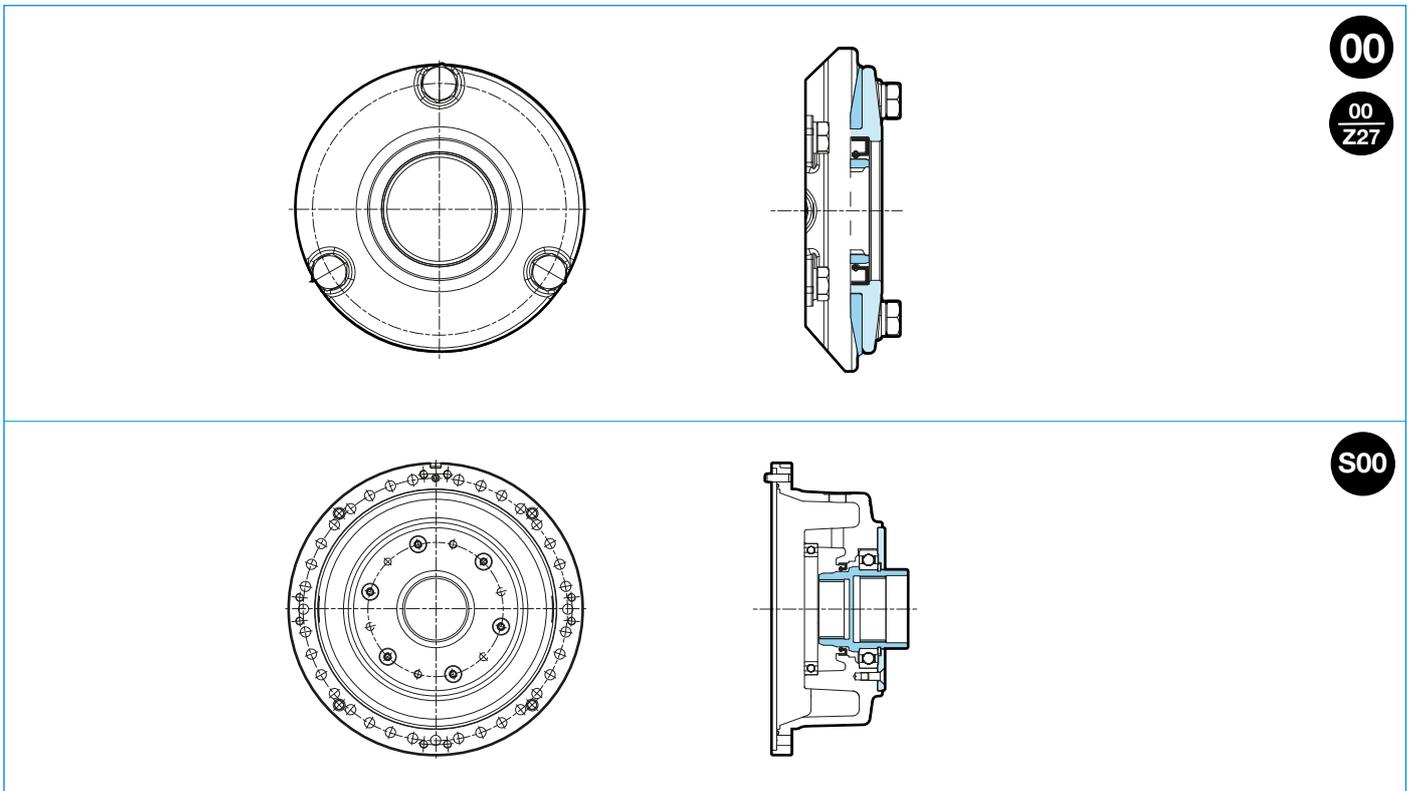

The dimension tables for the various sizes give the applicability.

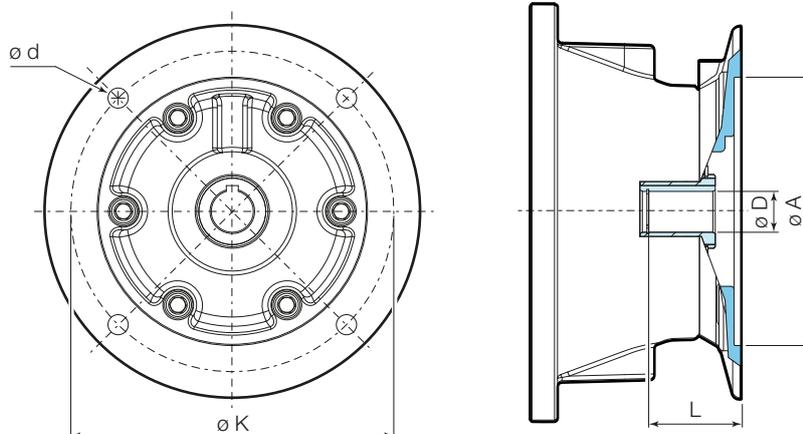

Universal inputs

Dimensions in inches
 In addition to the flanges given in the table, other models are available on request.

Supply status

Unless otherwise specified in the contract, the gearboxes are painted externally with an anticorrosive 2-component water-soluble epoxy resin based primer, blue RAL 5012.

The protection is suitable for withstanding normal industrial environments (also outdoors) and can be finished with synthetic, nitro-synthetic or 2-component enamel paints.

In case of particularly aggressive ambient conditions, it is necessary to use special painting cycles, which can be carried out on request. The machined external parts of the gearbox, such as the shaft ends, support surfaces, spigots, etc., must be protected with antioxidant oil (Tectyl).

The inside walls of the gearbox casings are painted with oil-proof paint and the kinematic mechanisms are protected with antioxidant oil. Unless otherwise specified in the contract, all gearboxes are supplied without lubricant, as shown by a special sticker applied to the gearbox to indicate its condition.

The gearboxes are packed and shipped in crates or on pallets able to withstand normal industrial environments.

Each gearbox comes with an "Installation and Maintenance Manual", "Manufacturer's Declaration" and "Certificate of Conformity" 2.1 according to EN10204.

Storage conditions

If the product is to be stored for more than 2 months:

protect shafts and spigots with a film of grease or corrosion protection products

- fill the gearbox completely with the lubricant required for the application
- store in a dry place with a temperature from -5 °F to +30 °F
- protect the gearbox from dirt, dust and damp
- always place a wooden support or other material between the gearbox and the ground to prevent direct contact with the ground.

When storing for more than 1 year, the rotary seals will lose efficiency. In this case, it is advisable to carry out a periodic check by turning the input shaft by hand to rotate the gears.

If there is a negative multi-disc brake, release the brake with a hydraulic pump or similar (see the "Oil bath multi-disc brakes" section for the brake release pressure).

At start-up, it is advisable to replace the seals.

General

The gearboxes must be carefully installed by suitably trained technical personnel.

Preparation for operation must occur in compliance with all the technical specifications given on the reference Dimensional Drawing.

All installation operations must ensure:

1. safety of operators and third parties
2. correct gearbox operation
3. safe operation

In this respect:

- any arbitrary tampering with the gearbox and with any accessories originally provided is strictly prohibited
- when lifting and transporting, do not knock the shaft ends and use specific lifting straps or the eye-bolts provided for this purpose, and make sure that the lifting equipment has adequate lifting capacity
- never carry out welding work on gearboxes.
- only carry out installation or maintenance work with the gearbox stationary. It is therefore advisable to ensure that the driving force cannot be activated unintentionally.
- regarding the gearbox input, electric or hydraulic motors are often mounted with the DANA 00 universal flange system (see the "Universal Input" section). Note that the 00 flange is normally used for motors weighing up to approximately 100 kg and 1000 ftlb of maximum torque. Specific adapters can be used with heavier motors: in this case, please contact your local DANA representative.
- with connections involving the use of rotating parts such as shafts, couplings or pulleys with belts, always provide adequate accident-prevention protection.

For flange-mounted gearboxes, we recommend observing the following requirements:

- the structures to which the gearboxes are secured must be rigid, with flat machined support surfaces that are free of paint, perpendicular to the driven shaft, and centred with a tolerance of H8.
- the mating surfaces must be perfectly degreased in advance.
- take care to align the gearbox with the driven shaft, especially with gearboxes that have splined female outputs, which cannot take external radial or axial loads.
- use at least class 10.9 screws with 75% tightening yield strength for fastening
- during assembly, take care to avoid violent axial impacts that could damage the inner bearings.
- the drive parts to be keyed to the output must be machined as specified in the "Outputs" section.

Note:

For right-angle gearboxes with male input shafts, the input shaft may not be in its ideal position during installation. To remedy this situation, we recommend:

- when connecting with couplings that are able to recover misalignments, measure the existing misalignment and check that it is acceptable for the coupling; if the misalignment is too big, shim the motor to bring it within the permissible play
- when connecting with mechanical parts that do not allow an play adjustment, align the motor using shims.

Shaft mounting

Before mounting, carefully clean the mating surfaces and lubricate them with suitable anti-seizure products (except for versions with FS hollow shafts - see the "Shrink disc" section).

Installation and removal must be carried out with suitable equipment, such as pullers and puller screws, using the threaded holes provided on the shafts; in any case, avoid any impacts or shocks that could cause permanent damage to the internal parts of the gearbox.

For the sizes of the driven shaft, refer to the section "Outputs".

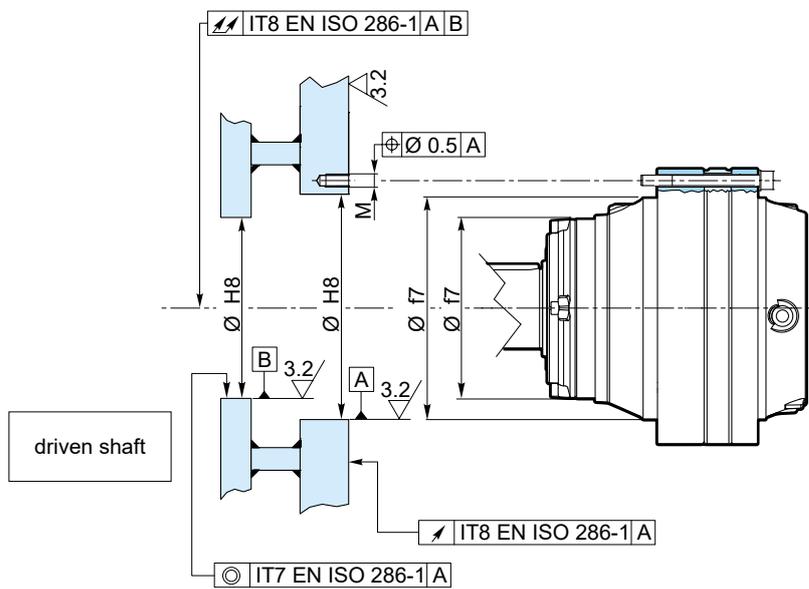

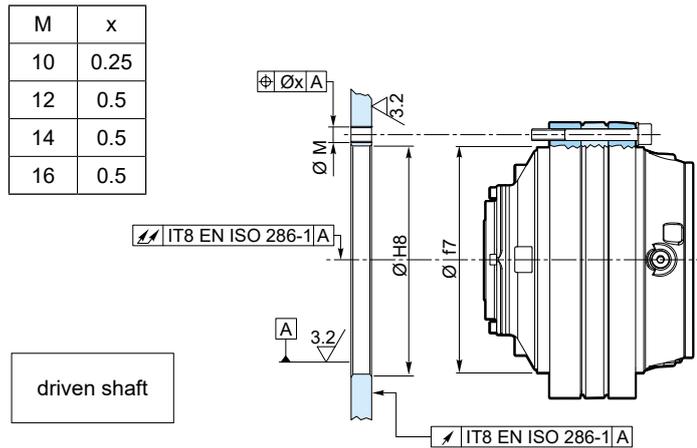

Flange support mounting

The mating surfaces must be machined with a degree of finish that ensures the required coefficient of friction (approx. Ra 3.2 in). To ensure alignment between the gearbox, motor and driven machine, observe the tolerances given in the diagrams below.

Before installation, clean and degrease the mating surfaces thoroughly, removing any traces of paint.

If the maximum torque to be transmitted is higher than $0.7 \times T_{2MAX}$, or if frequent reversals are foreseen, apply a suitable adhesive product for clamping on the coupling surfaces.

Installation must ensure the alignment of the gearbox and the shaft to be driven, or the gearbox and the motor whenever the motor is not directly flange-mounted to the gearbox.

A particularly important measure to prevent stress on the gearbox support flanges even during mounting, is to ensure that the mounting counter-flange adheres perfectly to the gearbox flange before tightening the fastening screws.

Fastening screws

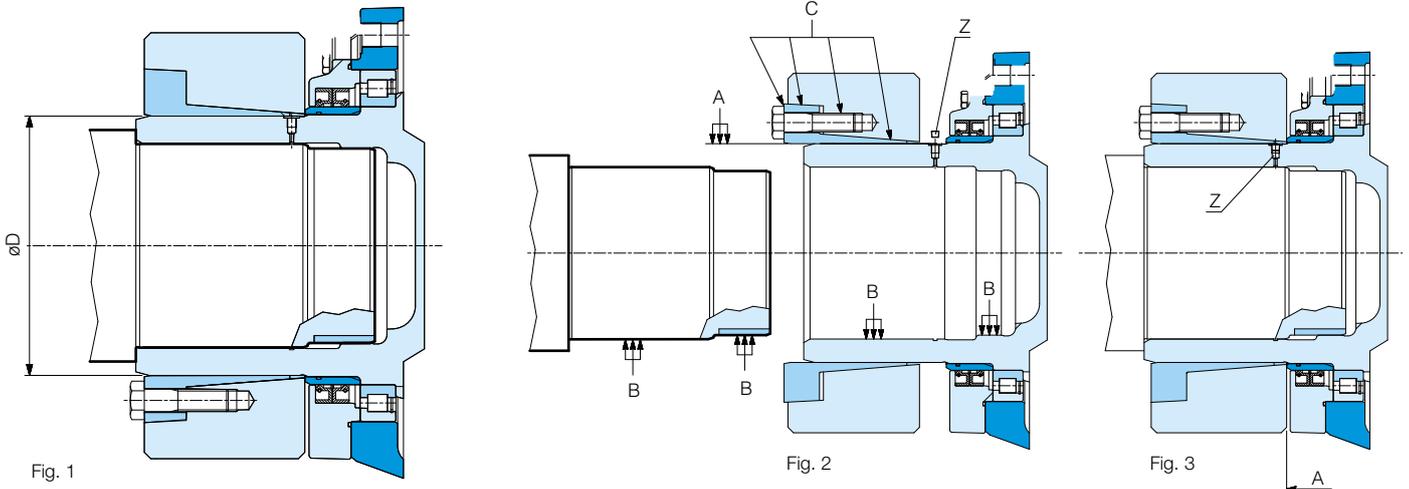

Secure the gearboxes with class 10.9 screws with ISO 7089 washers (300 HV min.)

The screws must be tightened (depending on their size) according to the torque values given in the dimension table for the specific size; the tightening torque values refer to screws in the conditions of supply, or with phosphate coating.

Do not lubricate the screws before tightening, as the consequent variation in surface friction coefficient of could overload the screws during tightening. Always check the tightening torque of the screws after the first few hours of machine operation.

Shrink discs are not supplied pre-installed on gearboxes and must be ordered separately. They are designed to be mounted on FS output. Given below are the characteristics and measures to be considered for correct assembly and disassembly of these parts used for the transmission of motion.

T_N : Nominal gearbox torque
 T_{GN} : Nominal coupling torque
 D: Shaft diameter

1. Thoroughly clean and degrease the shaft and its seat (see point B). To facilitate subsequent removal, it is advisable to make the small spigot for the shaft from a suitably machined bushing.
2. Lubricate the coupling seat (see point A) with molybdenum disulfide grease (MoS_2). When new, the coupling does not have to be disassembled for greasing. Greasing of the areas C is advisable only when reinstalling a used coupling.
3. Fit the coupling on the gearbox without tightening the screws. If the mounting position is vertical and the respective shaft is facing downward, make sure the coupling cannot slip off and fall. In all cases, never tighten the screws before fitting the shaft in its seat.
4. Fit the shaft in its seat. Mounting must take place without any interference, and this is only possible with precise gearbox/shaft alignment using suitable lifting equipment.

CAUTION!

Assembly must be carried out without applying axial forces, blows or impacts that could damage the gearbox bearings.

5. Fit the coupling up against the shoulder on the shaft before tightening the screws.
6. Tighten the screws gradually in a circular order, using a suitable torque wrench set to the tightening torque specified in the table below. Carry out final tightening, setting the wrench to a torque of 3-5% higher than that indicated.

Set the wrench to the torque specified in the table and make sure that no screws can be tightened further, otherwise repeat the procedure from point 5.

Mounting is complete and correct if the front surfaces of the inner and outer ring are at the same level.

The tightening torque does not have to be rechecked after the coupling is put into service.

7. Protect the coupling area with suitable sheet metal casing (point P) if there is risk of stones, sand or other material damaging the coupling or the gearbox seals.

Disassembly

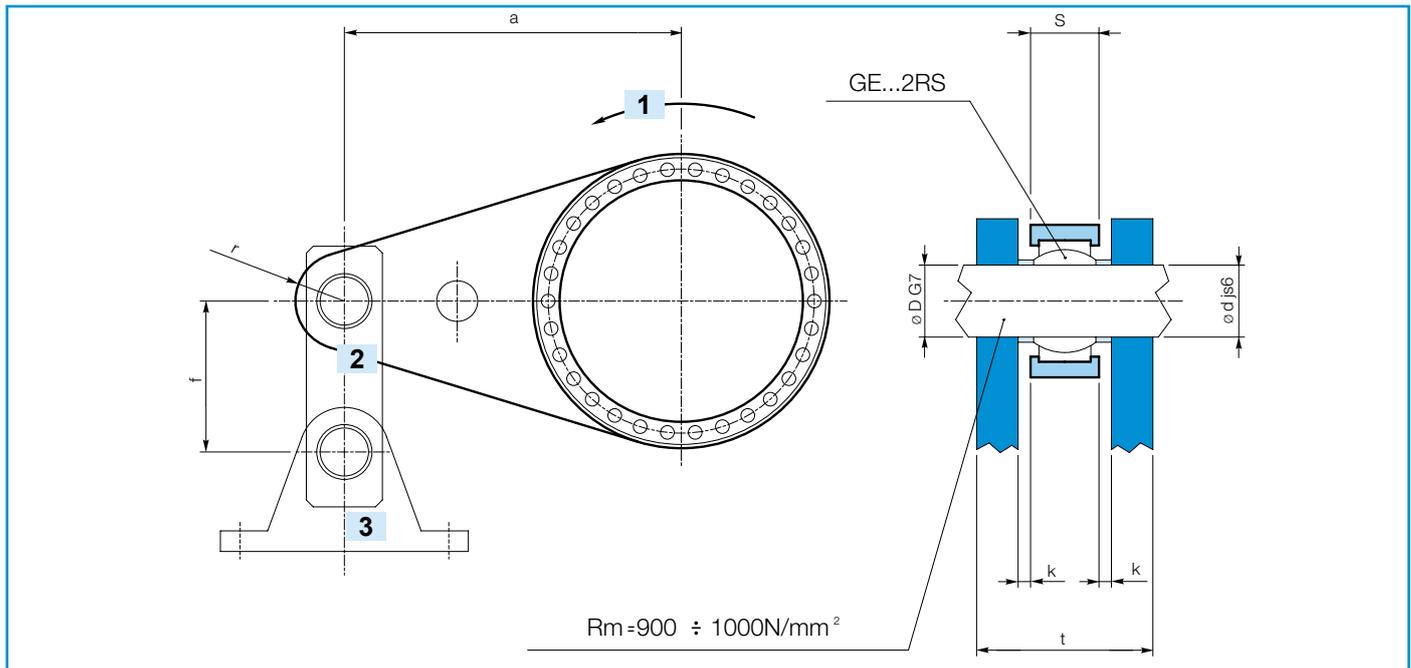

- 1) Loosen the screws "d" in several passes and in sequence so that the coupling can move on the hub.
CAUTION! Do not undo the screws completely so that the rings can separate on their own. High axial forces could cause violent removal, resulting in a hazard to operators.
- 2) This normally releases the clamping unit. Use suitable equipment to support the gearbox and separate the gearbox from the machine shaft.

CAUTION!

Refer to the maintenance manual to check the permissible axial loads.

Mounting the arm

- The torque arm must be free to move axially and have enough play in the couplings to allow small gearbox oscillations (always present) without overloading the gearbox. Therefore ball joints must be used in all connections.
- It is advisable to use long-life ball joints in which the rubbing surfaces are protected with PTFE. Alternatively, "steel to steel" joints can be used, provided they are greased periodically.
- The anchoring connecting rod must be parallel to the torque arm in order to ensure the side clearance "k" (unloaded), which ensures free movement of the structure in case of deformation.
- The fixed support to which the second end of the connecting rod is connected must ensure adequate anchorage for the load.
- The torque arm and corresponding connecting rod may have different design solutions from those proposed, but the following measures must be taken:

CAUTION!

Do not carry out any welding work involving the gearbox, not even earthing.

- Always use a torque wrench to tighten the coupling screws.
- The drawing is only by way of example, since the correct configuration depends on the gear unit rotation direction. In fact, during work it is advisable for the connecting rod to be in traction and not compression. Therefore mounting on the opposite side with respect to that represented may be convenient. If necessary, due to specific encumbrance the connecting rod can be assembled upwards.
- When carrying out an assembly by means of friction coupling and torque arm, remember that the weights of the gear unit, the torque arm and all the elements connected to them, bring about loads and tipping moments that are supported by the output stage planetary carrier bearings. Therefore the relative position of all the masses involved in transmitting power must be appraised in the design phase, in order to minimize the resultant value on the bearings. Likewise, the weight of the components connected to the gear unit must be limited, carefully appraising the thicknesses of the structures actually necessary for supporting the stresses, and decentralizing all the elements not involved in power transmission. An incorrect design can shorten the life of the bearing and gears due to possible excessive elastic deformation of the stages and determine the possibility of slipping and seizing of the friction coupling.

Click **DANA** button to return to section indexClick *i* button to return to main index

DANA gearboxes are supplied without lubricant; therefore the user must fill them correctly before starting the machine.

Essential oil specifications

The important parameters to consider when choosing the oil type are:

- viscosity under nominal operating conditions
- additives

The same oil must lubricate the bearings and the gears and all these components work inside the same box, in different operating conditions.

Viscosity

Nominal viscosity refers to a temperature of 40 °F, but decreases rapidly as the temperature increases. If the gearbox operating temperature is from 50 °F to 70 °F, a nominal viscosity can be chosen from the following guide table; choose the highest viscosity if a higher operating temperature is expected.

Output speed n_2 [rpm]	Working temperature	
	122° F	158° F
$n_2 \geq 20$	VG 150	VG 220
$5 < n_2 < 20$	VG 220	VG 320
$n_2 \leq 5$	VG 320	VG 460

Special attention must be paid to highly loaded output stages and those with very low speeds (<1 rpm). In such cases, always use high viscosity oils and with a good amount of Extreme Pressure (EP) additive.

Additives

In addition to the normal anti-foam and antioxidant additives, it is important to use oils with additives offering EP (extreme-pressure) and anti-wear properties, according to ISO 67436 L-CKC or DIN 515173 CLP. The lower the gearbox output speed, the more marked the EP characteristics of the products have to be. It should be remembered that the chemical compounds replacing hydrodynamic lubrication are formed to the detriment of the original EP load.

Therefore in case of very low speeds and high loads, it is important to observe the maintenance intervals so as not to lower the lubricating properties of the oil excessively.

Oil types

Oil types

The oils available generally belong to three large families.

- Mineral oils
- Polyalphaolefin (PAO) synthetic oils
- Polyalkylene glycol (PAG) synthetic oils

The most suitable choice is generally tied to the conditions of use.

Gearboxes that are not particularly loaded and with an intermittent operating cycle but without considerable temperature ranges can be lubricated with mineral oil.

In cases of heavy use, when the gearboxes are highly and continuously loaded resulting in a temperature increase, it is best to use polyalphaolefin synthetic lubricants.

The use of polyalkylene glycol oils is not allowed as they are not compatible with other oils and are often completely mixable with water; this phenomenon is particularly dangerous because it can go unnoticed, but rapidly diminishes the lubricating properties of the oil. Moreover, these lubricants may chemically attack the oil seals and paint inside the gearbox.

In addition to the above, there are also hydraulic oils and oils for the food industry.

The former are used for negative brakes.

The latter are used specifically in the food industry as they are special products that are not harmful to health.

The tables below contain lubricants offered by the best-known manufacturers, with specifications suitable for lubricating DANA gearboxes.

Contamination

During normal operation, due to run-in of the surfaces, metallic microparticles will inevitably form in the oil.

This contamination can shorten the life of the bearings, resulting in premature gearbox failure.

To limit and control this phenomenon, without resorting to frequent and costly oil changes, a suitable auxiliary oil circulation system with filtering and cooling of the oil must be provided.

This system offers the dual advantage of controlling the level of contamination through the use of special filters and stabilising the operating temperature at a level more suitable for ensuring the required viscosity.

For lubrication problems with gearboxes intended for special uses, it is advisable to contact your local DANA representative regarding the construction type and operating parameters.

Oil checking with unforced lubrication

Horizontal mounting

Levels

When the gearbox is mounted horizontally, the normal level to ensure correct lubrication is at the centre line, Fig. (A). For applications with very low output rotation speeds ($n_2 \leq 5$ rpm), it is advisable to fix the level at a value above 50–100 in. Fig. (B).

The correct level can be easily checked using a transparent tube positioned as shown in figure (B).

If the output speed is extremely low ($n_2 \leq 1$ rpm), or if long idle periods are expected, it is advisable to fill the entire box. In this case a special auxiliary tank must be provided.

To fit an instrument for visually checking the level (or by means of an electrical signal), mount it as shown in the diagram in Fig. (C).

Mount the breather plug above the sight glass with a tube that is long enough. Connect the top part (empty) of the gearbox just below the breather. This will prevent the leakage of oil.

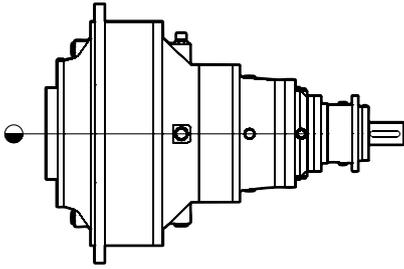

Fig. A

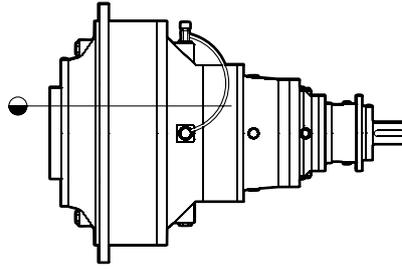

Fig. B

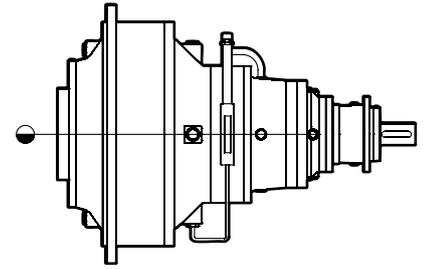

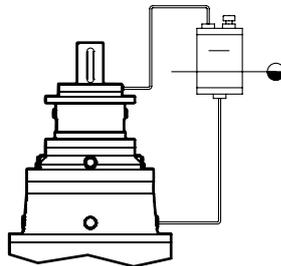

Fig. C

Expansion vessel

Several rules must be followed with vertical mounting, and in any case whenever the gearbox has to be filled completely.

During filling, an air bubble can form at the top, at the output shaft rotary seal, which must be eliminated to ensure that the seal is lubricated properly.

Also, since the oil volume increases with the temperature, an auxiliary tank must be provided to allow it to expand without creating hazardous pressures inside the gearbox.

For dimensioning, the oil expansion volume (V_e) must be determined at the operating temperature:

$$V_e = V_t \times \Delta T / 1800 \quad [\text{in}^3]$$

V_t = total oil volume

ΔT = difference between operating temperature and ambient temperature

The capacity (V_s) of the expansion vessel is:

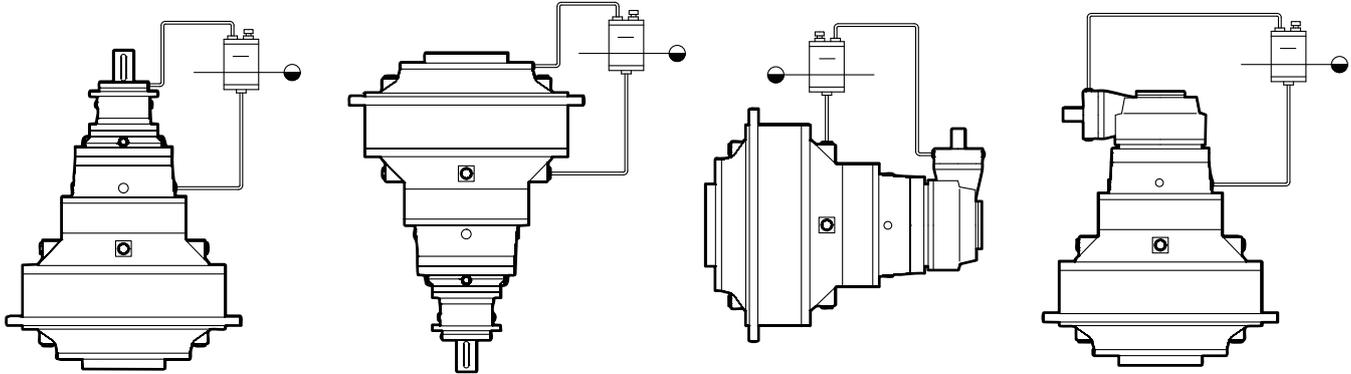

$$V_s = 2 \times V_e \quad [\text{in}^3]$$

To remove any residual air, the holes at the top of the gearbox and the top of the expansion tank must be connected; the latter must be located at a height that allows the gearbox to be filled up to the minimum level. It is advisable to make the bleed pipe or the expansion vessel with transparent material in order to easily check the exact position of the lubricant level.

Vertical in-line mounting and right-angle versions

The gearboxes must be completely full, so an expansion vessel must be fitted. As already mentioned, it is very important to connect the top gearbox breather to the expansion vessel to allow the oil to rise up to the rotary seal ring on the upper gearbox shaft.

When fitting an instrument for visual checking (or by means of a special electric signal), the instrument must be placed on the side of the tank.

Auxiliary cooling and filtering systems

If the power applied is greater than the thermal power that can be dissipated by the gearbox, an auxiliary cooling system (air-oil) must be used to dissipate the excess thermal power and keep the lubricating oil clean by means of constant filtering.

To fulfil this function, DANA offers a range of cooling units: contact your local DANA representative for details. The control units consist of an air-oil heat exchanger, a filter, an electric motor, a hydraulic pump with safety valve and a coaxial fan integral with the pump. If a different type of auxiliary system is to be fitted, make sure not to use systems with an external tank.

If an auxiliary tank is required (e.g. for cooling several gearboxes with a single system), we recommend contacting your local DANA representative. When designing an oil circulation circuit, it is advisable for the suction to be at the lowest point, so that this branch of the circuit can also be used to drain the gearbox.

In any case, the oil suction and delivery points must be far enough apart to ensure that fresh oil passes through the gearbox. The diameter of the oil holes is very important, especially in suction. In fact, the pump tends to cavitate if the holes are too small. Not being able to change the pump delivery, which is a function of the power to be dissipated, the capacity of the holes must be verified.

When sucking oil from the input supports or flanges of fast gearboxes, the use of one hole may be insufficient for the entire flow; therefore 2 or 3 holes must be connected by means of a manifold connected to the suction pipe.

Delivery is usually less problematic since, if the natural flow rate is too low, a small pressure is generated which ensures the flow.

For correct dimensioning of the circuit, it is advisable to follow these rules.

Suction:

- suck from several holes when the oil speed v_o is higher than 4.30 ft/s with just one hole;

Delivery:

- deliver to several holes when the oil velocity v_o is higher than 6.89 ft/s with just one hole.

The speed can be obtained from the table below, or calculated with the following equation:

$$v = (Q \times 0.405) / d^2 \quad [\text{ft/s}]$$

where:

- v = oil speed in [ft/s]
- Q = flow rate in [US gal/min]
- d = inside diameter of the union in [in]

The calculation takes the kinematic oil viscosity of 60 cSt into account.

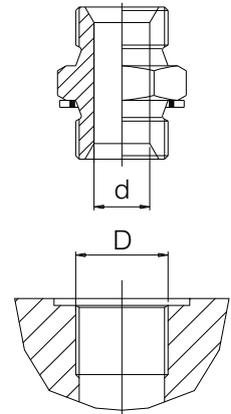

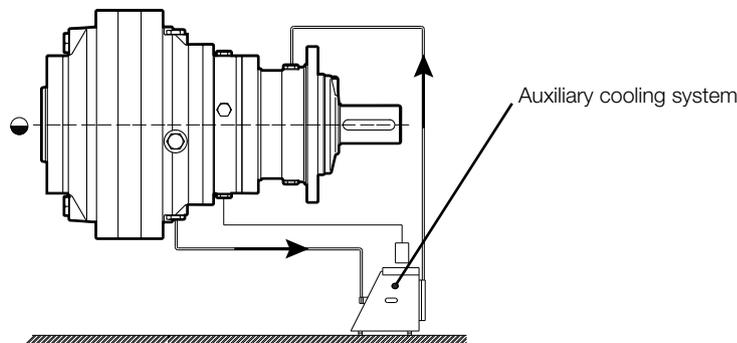

Fig. 15

Oil checking with auxiliary cooling system

In-line horizontal gearbox

Refer to the figure below to check the oil level and the position of the cooling circuit fittings.

In-line and right-angle vertical gearbox

Refer to Fig. (D), (E) and (F) to check the oil level and the position of the cooling circuit fittings.

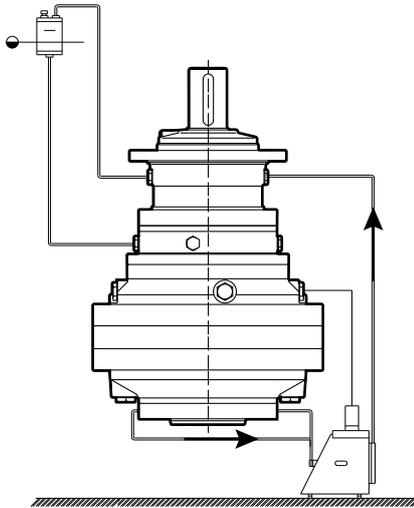

Fig. D

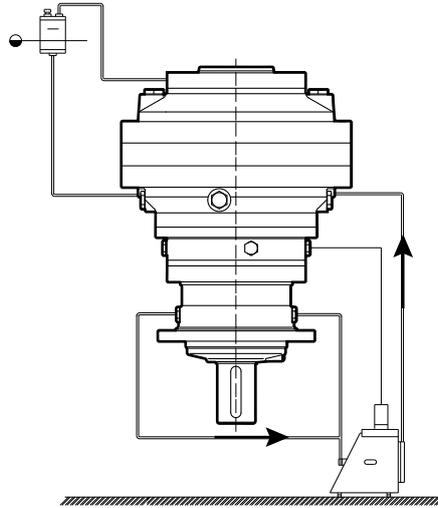

Fig. E

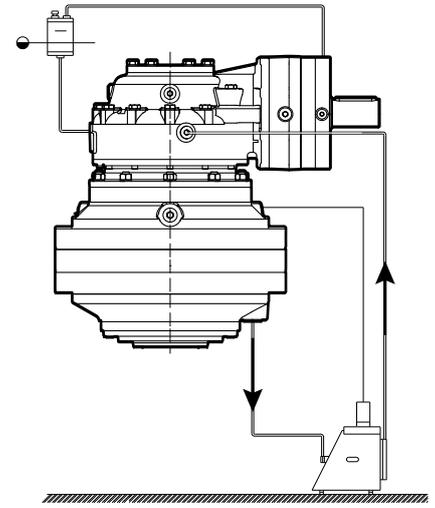

Fig. F

Caution

The auxiliary oil cooling and filtration systems described above are the minimum condition required to control the gearbox lubrication. The end-user can always extend the system by adding auxiliary safety checks on the flow, temperature and level.

The system may also be fitted with valves to facilitate oil changes with the aid of the service pump and auxiliary suction filter to protect the pump from unwanted debris from inside the gearbox.

Oil change

If there is no filtering and cooling circuit, the first oil change must be done after 500–600 hours of operation. Subsequently, the following oil change frequencies are recommended:

Oil temperature [°F]	Oil change interval [h]	
	Synthetic Oil	Mineral Oil
≤ 149	10'000	4'000
149 ÷ 176	8'000	3'000

In case of heavy duty applications, the above values must be halved. The values given in the table refer to a work environments free from external contamination.

It is advisable to carry out the oil change with the gearbox hot, (approximately 40°F) to prevent sludge from forming and to help it drain completely.

For the correct procedure, follow the rules given in the installation and maintenance manual supplied with each gearbox.

It is advisable to check the oil level periodically.

Check for leaks if more than 10% the total volume has to be added.

Lubricant quantity [US Gal]

The quantities of oil indicated are approximate and to be used for supply purposes.
The exact quantity of oil to be introduced into the reducer is defined by its level.

Technologies Customized to Every Part of the Globe

With a presence in 31 countries, Dana Incorporated boasts more than 150 engineering, manufacturing, and distribution facilities. Our worldwide network of local service centers provides assurance that each customer will benefit from the local proximity and responsiveness.

About Dana Incorporated

Dana is a leader in the design and manufacture of highly efficient propulsion and energy-management solutions that power vehicles and machines in all mobility markets across the globe. The company is shaping sustainable progress through its conventional and clean-energy solutions that support nearly every vehicle manufacturer with drive and motion systems; electrodynamic technologies, including software and controls; and thermal, sealing, and digital solutions. Founded in 1904, we employ thousands of people across six continents.

About Dana Off-Highway Drive and Motion Systems

Dana delivers fully optimized Spicer® drivetrain and Brevini® motion systems to customers in construction, agriculture, material-handling, mining, and industrial markets. We bring our global expertise to the local level with technologies customized to individual requirements through a network of strategically located technology centers, manufacturing locations, and distribution facilities.

Learn more about Dana's drivetrain and motion systems at dana.com/offhighway.
